**IN THE SPECIFICATION**

Please amend paragraph [32] as follows:

[32] After the intermediate product has been produced, the intermediate product, the spacer 18, and the fiber mat 16 are placed in the foaming mold and brought in position therein. The positioning can be carried out, for instance, in the upper mold half using a tensioning frame so that the barrier layer ~~14~~ 12 is situated at the side of the upper mold half facing the lower mold half. As a next step, the water-like liquid plastic mass, which has been mixed thoroughly in a mixing head, is applied to the fiber mat 16. The liquid plastic mass instantly infiltrates the fiber mat 16 and the spacer 18 and gets in direct contact with the barrier layer 12, partially penetrating the barrier layer 12. The upper mold half of the foaming mold is then laid on the lower mold half and the foaming mold is tightly sealed. Due to its elastic properties, the spacer 18 in combination with the displacement forces of the expanding plastic foam ensures that the optionally patterned surfaces of the mold halves will be reproduced. When a certain reaction time is over, the foaming mold is opened and the resultant one-piece vehicle interior lining is taken out of the foaming mold.
